

## Ecological site R028AY134UT Desert Sand (Four-Wing Saltbush)

Accessed: 05/12/2025

### General information

**Provisional.** A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

Figure 1. Mapped extent

Areas shown in blue indicate the maximum mapped extent of this ecological site. Other ecological sites likely occur within the highlighted areas. It is also possible for this ecological site to occur outside of highlighted areas if detailed soil survey has not been completed or recently updated.

### MLRA notes

Major Land Resource Area (MLRA): 028A—Ancient Lake Bonneville

This site occurs in MLRA 28A, LRU A, the northern part of MLRA 28A. This LRU has a mesic soil temperature regime and a typical aridic soil moisture regime. Typically most precipitation occurs in the winter. Mean annual precipitation is between 4 to 8 inches. The north desert ecological zone typically has no big sagebrush (*Artemisia tridentata* spp.), but typically is dominated by shadscale (*Atriplex confertifolia*), winterfat (*Krascheninnikovia lanata*), saltbushes (*Atriplex* spp), Indian ricegrass (*Achnatherum hymenoides*), and bottlebrush squirreltail (*Elymus elymoides*). Unlike the southern LRUs, there is typically very little if any galleta (*Pleuraphis jamesii*) grass.

### Classification relationships

MLRA 28A, LRU A, northern desert ecological zone

### Ecological site concept

This site is typically dominated by four-wing saltbush. It is found on deep sandy soils on the low slopes of alluvial fans, fan remnants, lake terraces or dunes.

| Slope     | 1–10%                                    |

## Climatic features

The climate is cold and snowy in the winter and warm and dry in the summer. The average annual precipitation is 5 to 8 inches. Approximately 70 percent comes as rain from March through October. On the average, June through September are the driest months and March through May are the wettest months.

Climate data from PRISM model.

Mean Annual Air Temperature: 45-50

Mean Annual Soil Temperature: 50-53

## Influencing water features

### Soil features

The characteristic soils in this site are over 60 inches deep and excessively well drained.

They formed in alluvium and aeolian deposits derived mainly from mixed parent materials. The surface horizon is loamy sand textures and 5 inches thick. About 35 percent of the soil surface is covered by rock fragments. The volume of rock fragments in the soil profile is 0 to 5 percent.

Soils in this site have coarse textures throughout the profile including sands and loamy sand. Some soils have a

layer of carbonate accumulation at a depth of 6 to 20 inches. The available water capacity is 3 to 5 inches. The permeability is rapid. Runoff is slow.

The water supplying capacity is 2 to 5 inches. Natural geologic erosion in potential is approximately 0.5 tons/acre/year.

**Table 4. Representative soil features**

|  |  |
|--|--|
| Surface texture  | (1) Loamy fine sand<br>(2) Fine sand<br>(3) Sand |
| Drainage class   | Well drained to somewhat excessively drained     |
| Permeability class                                       | Rapid  |
| Soil depth   | 152 cm   |
| Surface fragment cover <=3"                              | 0–11%  |

| Subsurface fragment volume >3"<br>(Depth not specified)  | 0%   |

## Ecological dynamics

As ecological condition deteriorates due to overgrazing, Indian ricegrass, needle and thread, galleta, and fourwing saltbush decrease while rabbitbrush, annual forbs, and annual grasses increase.

When the potential natural plant community is burned needle and thread and Indian ricegrass decrease while rabbitbrush and annuals increase.

Annual forbs are most likely to invade this site.

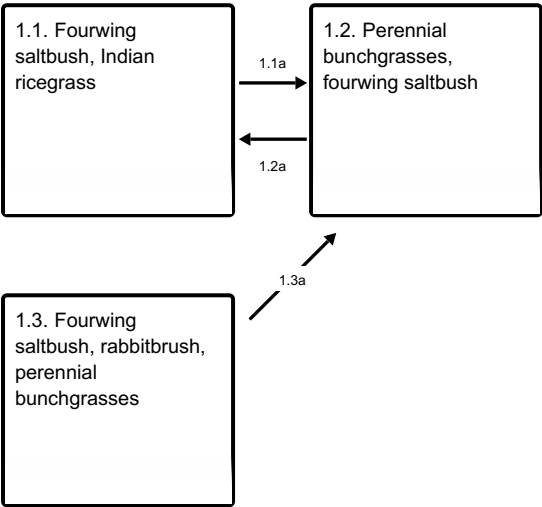

This site is similar to Nevada's 028AY011NV ecological site and the STM developed for 011NV is used below (Stringham et al. 2015).

## State and transition model

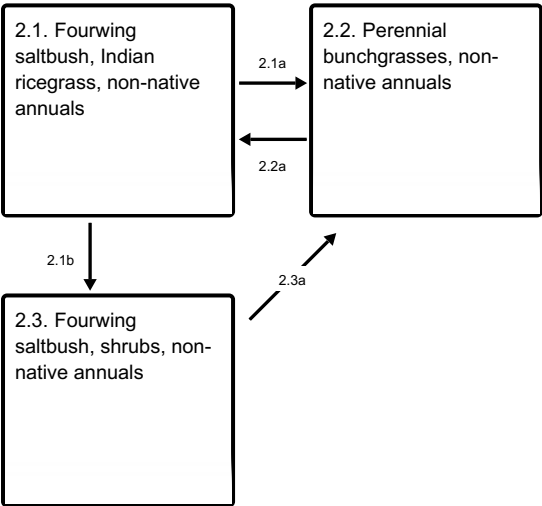

Ecosystem states

State 1 submodel, plant communities

State 2 submodel, plant communities

State 3 submodel, plant communities

## State 1

### Reference State

The Reference State 1.0 is a representative of the natural range of variability under pristine conditions. The reference state has three general community phases; a shrub-grass dominant phase, a perennial grass dominant phase and a shrub dominant phase. State dynamics are maintained by interactions between climatic patterns and disturbance regimes. Negative feedbacks enhance ecosystem resilience and contribute to the stability of the state. These include the presence of all structural and functional groups, low fine fuel loads, and retention of organic matter and nutrients. Plant community phase changes are primarily driven by fire, periodic long term drought and/or insect or disease attack.

## Community 1.1

### Fourwing saltbush, Indian ricegrass

The dominant aspect of the plant community is fourwing saltbush and Indian ricegrass. The composition by air-dry weight is approximately 45 percent perennial grasses, 10 percent forbs, and 45 percent shrubs.

Table 5. Annual production by plant type

| Plant Type      | Low<br>(Kg/Hectare) | Representative Value<br>(Kg/Hectare) | High<br>(Kg/Hectare) |

## Community 1.2

### Perennial bunchgrasses, fourwing saltbush

This community phase is characteristic of a post-disturbance, early-seral community phase. Indian ricegrass, and other perennial bunchgrasses dominate. Fourwing saltbush may sprout after fire depending on ecotype. Black greasewood, spiny hopsage and other sprouting shrubs may increase.

## Community 1.3

### Fourwing saltbush, rabbitbrush, perennial bunchgrasses

Fourwing saltbush and other shrubs increase in the absence of disturbance. Excessive herbivory may cause an increase in black greasewood and other unpalatable shrubs. Fourwing saltbush and other shrubs dominate the overstory and the deep-rooted perennial bunchgrasses in the understory are reduced either from competition with shrubs and/or from herbivory.

## Pathway 1.1a

### Community 1.1 to 1.2

Fire will decrease or eliminate the overstory of fourwing saltbush and allow for the perennial bunchgrasses to dominate the site. Fires will typically be low severity due to dispersed fuel loads. A fire following an unusually wet spring facilitating an increase in fine fuels may be more severe and reduce fourwing saltbush cover to trace amounts.

## Pathway 1.2a

### Community 1.2 to 1.1

Absence of disturbance over time allows fourwing saltbush and other shrubs to recover.

## Pathway 1.3a

### Community 1.3 to 1.2

A low severity fire, herbivory or combinations will reduce the fourwing saltbush overstory and create a fourwing saltbush/grass mosaic.

## State 2

## **Current Potential State**

This state is similar to the Reference State 1.0. This state has the same three general community phases. Ecological function has not changed, however the resiliency of the state has been reduced by the presence of invasive weeds. Non-natives may increase in abundance but will not become dominant within this State. These non-natives can be highly flammable and can promote fire where historically fire had been infrequent. Negative feedbacks enhance ecosystem resilience and contribute to the stability of the state. These feedbacks include the presence of all structural and functional groups, low fine fuel loads, and retention of organic matter and nutrients. Positive feedbacks decrease ecosystem resilience and stability of the state. These include the non-natives' high seed output, persistent seed bank, rapid growth rate, ability to cross pollinate, and adaptations for seed dispersal.

### **Community 2.1**

#### **Fourwing saltbush, Indian ricegrass, non-native annuals**

Fourwing saltbush and Indian ricegrass dominate the site. Black greasewood, spiny hopsage and other shrubs are also common. Alkali sacaton, thickspike wheatgrass and bottlebrush squirreltail are also present in the understory. Forbs are present but not abundant. Non-native annual species are present.

### **Community 2.2**

#### **Perennial bunchgrasses, non-native annuals**

This community phase is characteristic of a post-disturbance, early seral community phase. Indian ricegrass and other perennial grasses dominate. Fourwing saltbush may be killed by fire depending on ecotype, therefore it may decrease in the burned community. Depending on fire severity patches of intact fourwing saltbush may remain. Sprouting shrubs such as black greasewood, spiny hopsage and rabbitbrush may dominate the aspect for a number of years following fire. Annual non-native species generally respond well after fire and may be stable to increasing within the community.

### **Community 2.3**

#### **Fourwing saltbush, shrubs, non-native annuals**

Fourwing saltbush increases in the community and may become the dominant with lack of disturbance. Inappropriate grazing may cause a decrease in fourwing saltbush and allow other shrubs such as black greasewood, spiny hopsage and shadscale to increase.

### **Pathway 2.1a**

#### **Community 2.1 to 2.2**

Fire would decrease or eliminate the overstory of fourwing saltbush and allow for the perennial bunchgrasses to dominate the site. Fires would typically be small and patchy due to low fuel loads. A fire following an unusually wet spring or a change in management facilitating an increase in fuel loads may be more severe and reduce shrub cover to trace amounts. Annual non-native species generally respond well after fire and may be stable or increasing in within the community.

### **Pathway 2.1b**

#### **Community 2.1 to 2.3**

Time and lack of disturbance and/or chronic drought allows for fourwing saltbush to increase and dominate the site, causing a reduction in the perennial bunchgrasses. Inappropriate grazing may cause a decrease in perennial bunchgrasses and fourwing saltbush allowing other shrubs such as black greasewood and spiny hopsage to increase. However bottlebrush squirreltail and thickspike wheatgrass may increase in the understory depending on the grazing management.

### **Pathway 2.2a**

#### **Community 2.2 to 2.1**

Time and lack of disturbance may allow for fourwing saltbush and other shrubs to establish and increase in community.

### **Pathway 2.3a**

#### **Community 2.3 to 2.2**

Low severity fire, grazing management or combinations may decrease fourwing saltbush allowing for the perennial understory to increase. Late fall/winter grazing may cause mechanical damage to other shrubs such as black greasewood and spiny hopsage promoting the perennial bunchgrass understory.

### **State 3**

#### **Shrub State**

This state has two community phases and is a product of many years of heavy grazing during time periods harmful to perennial bunchgrasses. Black greasewood, spiny hopsage and rabbitbrush dominate the overstory. Shrub cover exceeds site concept and may be decadent, reflecting stand maturity and lack of seedling establishment due to competition with mature plants. The shrub overstory dominates site resources such that soil water, nutrient capture, nutrient cycling and soil organic matter are temporally and spatially redistributed. With a decrease in understory species the soils on these sites may become unstable and wind erosion may increase.

#### **Community 3.1**

##### **Shrub dominated, non-native annuals**

Black greasewood dominates the overstory. Rabbitbrush and spiny hopsage may be significant components. Fourwing saltbush is still present but declining. Deep-rooted perennial bunchgrasses may be present in trace amounts or absent from the community. Annual non-native species increase. Bare ground is significant.

#### **Community 3.2**

##### **Shrub and non-native annual dominated**

Black greasewood, rabbitbrush and spiny hopsage dominate the site. Fourwing saltbush may be found in trace amounts or may be absent from the site. Annual non-native species dominate the understory. Perennial bunchgrasses make up a minor component.

### **Pathway 3.1a**

#### **Community 3.1 to 3.2**

Heavy grazing in winter and early spring decreases fourwing saltbush and perennial bunchgrasses, and may promote other shrubs such as rabbitbrush and black greasewood.

### **Transition T1A**

#### **State 1 to 2**

Trigger: This transition is caused by the introduction of non-native annual weeds, such as cheatgrass, mustards, and Russian thistle. Slow variables: Over time the annual non-native species will increase within the community. Threshold: Any amount of introduced non-native species causes an immediate decrease in the resilience of the site. Annual non-native species cannot be easily removed from the system and have the potential to significantly alter disturbance regimes from their historic range of variation.

### **Transition T2A**

#### **State 2 to 3**

Trigger: To Community Phase 3.1: Inappropriate cattle/horse grazing will decrease or eliminate deep rooted perennial bunchgrasses and fourwing saltbush and favor other shrub growth and establishment. Soil disturbing brush treatments will reduce fourwing saltbush and possibly increase non-native annual species and rabbitbrush. Slow variables: Long term decrease in deep-rooted perennial grass density and/or fourwing saltbush. Threshold: Loss of deep-rooted perennial bunchgrasses changes nutrient cycling, nutrient redistribution, and reduces soil organic matter. Loss of long-lived, fourwing saltbush changes the temporal and depending on the replacement shrub, the spatial distribution of nutrient cycling.

## Additional community tables

## Animal community

This site is suited for sheep and cattle grazing during winter and spring.

Wildlife using this site include rabbit, coyote, fox, pronghorn antelope, and mule deer (seasonal).

This is a short list of the more common species found. Many other species are present as well and migratory birds are present at times.

## Hydrological functions

The soils are in hydrologic group A with runoff curves ranging from 39 to 69 depending on hydrologic condition.

## Recreational uses

Hiking and Camping

## Wood products

None

## Other information

Threatened and endangered species include plants and animals.

## Type locality

## Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be

known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

## Indicators

- 1. Number and extent of rills:** Minor rill development may be evident in the reference community only following a recent significant storm or snow melt events. Rill presents may be more evident where run-on from adjacent upland sites or exposed bedrock concentrate flows. Any rill development will be short (< 5') and spaced 6' – 8'. Evidence of rills will decrease in the months following major weather events due to the affects of wind on this sites very coarse textured surface soil.

---
- 2. Presence of water flow patterns:** Slight evidence of water flow may be evident in the reference community following significant storm events. Flow patterns affect < 5% of the site. Flow patterns are normally <20 feet long, follow natural contours, and are typically spaced 10 to 15 feet apart.

---
- 3. Number and height of erosional pedestals or terracettes:** Very minor pedestal development caused by wind erosion is evident in the reference community, but there should be no exposed roots. 1 – 3 inches of depositional mounding in Indian ricegrass bunches, and under Four-wing saltbush canopies are normal. Some evidence of wind generated soil movement is evident; any unstable areas present have mostly healed over.

---
- 4. Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):** Bare ground ranges from 20% - 40% in the reference community. Ground cover (the inverse of bare ground) typically includes: coarse fragments – 2% to 5%; plant canopy – 20% to 30%; litter – 20% to 30%.

---
- 5. Number of gullies and erosion associated with gullies:** Developed gully channels are a normal component of desert environments. Gullies associated with the reference state will typically have stable, partially vegetated sides and bottoms with no evidence of head-cutting. Some evidence of disturbance may be evident following significant weather events or when gullies convey runoff from higher elevation rocky or naturally eroding areas.

---
- 6. Extent of wind scoured, blowouts and/or depositional areas:** Some evidence of wind generated soil movement is normal in reference communities on this site. Evidence of small (100 sq feet) wind generated blowouts may also be present; any blowout areas present appear stable and are being stabilized with perennial vegetation. Some depositional mounding around Indian ricegrass bunches, and under fouwing saltbush canopies is a normal characteristic of this site.

---
- 7. Amount of litter movement (describe size and distance expected to travel):** Most litter resides in place within or

under plant canopies. Some movement of fine material ( $< \frac{1}{4}$ " ) may move (2' – 4') in the direction of prevailing winds or down slope if being transported by water. Some accumulation is observed behind obstructions. Larger woody litter ( $> \frac{1}{2}$ " ) is mostly found under or near shrubs.

---

8. **Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values):** This site should have a soil stability rating of 2 to 4. Surface textures are typically coarse loamy sands containing 0% to 5% coarse fragments.
  9. **Soil surface structure and SOM content (include type of structure and A-horizon color and thickness):** Soil surface ranges from 5 to 12 inches deep and structure is very weak to weak, thin platy. The A-horizon color range from 10YR 6/3 to 10YR7/3. Soils have an Ochric epipedon that extends 5 to 12 inches into the soil profile. The A horizon is normally deeper and better developed under plant canopies.
  10. **Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff:** The presence of rhizomatous grasses such as James galleta or Western wheatgrass combined with healthy perennial bunchgrasses and Four-wing saltbush in the reference community provides for the best infiltration and least runoff from storm events and snow melt. As perennial vegetation decreases and bare ground increases, runoff increases and soil loss is accelerated.
  11. **Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site):** None. Soils are deep to very deep.
  12. **Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):**

Dominant: Dominant: cool season grasses (e.g. Indian ricegrass and Needleandthread) 30 – 40%, > Sprouting shrubs (e.g. Four-wing saltbush and Winterfat) 20 – 30%.

Sub-dominant: Sub-dominant: Sprouting shrubs (e.g. Spiny hopsage and Rubber rabbitbrush) 5 – 15%, > warm season grasses (e.g. Galleta) 5 – 10%, > Cool season grasses (e.g. Western wheatgrass and Bottlebrush squirreltail) 1-3%.

Other: Others: Shrubs (e.g. Shadscale and Bud sage 1-3%), perennial forbs (e.g. Scarlet globemallow and Cushion wild buckwheat) 3-5%, biological soil crusts (e.g. lichens, mosses, cyanobacteria) trace%.

Additional: Moss and lichen communities will normally be found under plant canopies while the cyanobacteria will be found throughout the site. Functional/structural groups may appropriately contain non-native species if their ecological function is the same as the native species in the reference state. Perennial and annual forbs can be expected to vary widely in their expression in the plant community based upon departures from average growing conditions.
  13. **Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence):** During years with average to above-average precipitation, there should be very little recent mortality or decadence apparent in either the shrubs or grasses. There may be partial ( $< 30\%$ ) mortality of individual bunchgrasses and other shrubs during severe drought.
-

14. **Average percent litter cover (%) and depth ( in):** Litter cover ranges from 20 to 30% with a spike when shrubs drop their leaves. Depth varies from  $\frac{3}{4}$  to  $\frac{1}{2}$  inch with depth increasing near plant canopies.
- 

15. **Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production):** 450 - 550 pounds on an average year.
- 

16. **Potential invasive (including noxious) species (native and non-native).** List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site: Broom snakeweed, Russian thistle, Redstem storksbill, annual bromes and Halogeton are likely to increase in or invade this site.
- 

17. **Perennial plant reproductive capability:** All perennial plant species have the ability to reproduce in most years except drought years.
