

Ecological site R041XC316AZ Sandy Wash 12-16" p.z.

Accessed: 05/13/2025

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

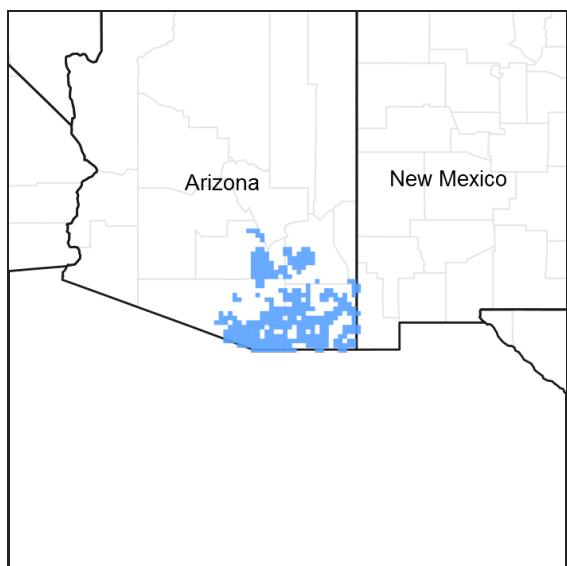

Figure 1. Mapped extent

Areas shown in blue indicate the maximum mapped extent of this ecological site. Other ecological sites likely occur within the highlighted areas. It is also possible for this ecological site to occur outside of highlighted areas if detailed soil survey has not been completed or recently updated.

MLRA notes

Major Land Resource Area (MLRA): 041X—Madrean Archipelago

AZ 41.3 – Chihuahuan – Sonoran Semidesert Grasslands

Elevations range from 3200 to 5000 feet and precipitation ranges from 12 to 16 inches per year. Vegetation includes mesquite, catclaw acacia, netleaf hackberry, palo verde, false mesquite, range ratany, fourwing saltbush, tarbush, littleleaf sumac, sideoats grama, black grama, plains lovegrass, cane beardgrass, tobosa, vine mesquite, threeawns, Arizona cottontop and bush muhly. The soil temperature regime is thermic and the soil moisture regime is ustic aridic. This unit occurs within the Basin and Range Physiographic Province and is characterized by numerous mountain ranges that rise abruptly from broad, plain-like valleys and basins. Igneous and metamorphic rock classes dominate the mountain ranges and sediments filling the basins represent combinations of fluvial, lacustrine, colluvial and alluvial deposits.

Herbaceous	Not specified

Physiographic features

This site occurs in the middle elevations of the Madrean Basin and Range province in southeastern Arizona. It occurs on floodplains, low stream terraces; in canyons and on alluvial fans. It benefits on a regular basis from extra moisture received as over-bank flooding of channels and as runoff from adjacent upland areas. It does not benefit from shallow water tables.

Table 2. Representative physiographic features

Landforms	(1) Flood plain (2) Stream terrace (3) Canyon
Flooding duration	Very brief (4 to 48 hours) to brief (2 to 7 days)
Flooding frequency	Occasional to frequent
Ponding duration	Very brief (4 to 48 hours)
Ponding frequency	None to rare
Elevation	975–1,524 m
Slope	0–3%
Aspect	Aspect is not a significant factor

Climatic features

Precipitation in this common resource area ranges from 12-16 inches yearly in the eastern part with elevations from 3600-5000 feet, and 13-17 inches in the western part where elevations are 3300-4500 feet. Winter-Summer rainfall ratios are 40-60% in the west and 30-70% in the east. Summer rains fall July-September, originate in the Gulf of Mexico and are convective, usually brief, intense thunderstorms. Cool season moisture tends to be frontal, originates in the Pacific and Gulf of California, and falls in widespread storms with long duration and low intensity. Snow rarely lasts more than one day. May and June are the driest months of the year. Humidity is generally very low.

Temperatures are mild. Freezing temperatures are common at night from December-April; however temperatures during the day are frequently above 50 F. Occasionally in December-February, brief 0 F temperatures may be experienced some nights. During June, July and August, some days may exceed 100 F.

Cool season plants start growth in early spring and mature in early summer. Warm season plants take advantage of summer rains and are growing and nutritious July-September. Warm season grasses may remain green throughout the year.

Table 3. Representative climatic features

Frost-free period (average)	220 days
Freeze-free period (average)	0 days
Precipitation total (average)	406 mm

Influencing water features

There are no water features associated with this site.

Soil features

These are very young soils on gravelly and sandy alluvium of mixed origin. They are deep and well drained. Surface textures range from gravelly sand to loamy fine sand. Sub-soils are sandy loam and loamy sands with various amounts of gravel and/or cobbles. Although coarse textures make for low available water holding capacities, plant-soil moisture relationships are very good due to extra moisture the site receives. Soil surfaces, outside of channel areas, are dark colored.

Soils mapped on this site include: SSA-661 Eastern Pinal & Southern Gila counties MU 6 Bodecker; SSA-663 Gila-Duncan area MU's 7 Camoro & Santo Tomas, 36 Santo Tomas; SSA-664 San Simon area MU 36 Santo Tomas; SSA-666 Cochise county Northwest part MU's 7 Bodecker and 52 Keesto; SSA-667 Santa Cruz area MU's CtB & GbB Comoro; SSA-669 Pima county Eastern part MU's 19 & 68 Comoro; SSA-671 Cochise county Douglas-Tombstone part MU's 9 Bodecker & Comoro, 10 Bodecker GrVSL, 11 Bodecker GrVSL saline-sodic, 33 Comoro SL, 34 Comoro SL saline-sodic, 94 Keesto and 127 Bodecker; SSA-703 Tohono O'odham Nation MU 38 Keesto.

Ecological dynamics

The plant communities found on an ecological site are naturally variable. Composition and production will vary with yearly conditions, location, aspect, and the natural variability of the soils. The Historical Climax Plant Community represents the natural potential plant communities found on relict or relatively undisturbed sites. Other plant communities described here represent plant communities that are known to occur when the site is disturbed by factors such as fire, grazing, or drought.

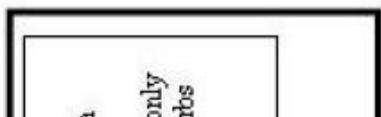

Production data provided in this site description is standardized to air dry weight at the end of the summer growing season. The plant communities described in this site description are based on near normal rainfall years.

NRCS uses a Similarity Index to compare existing plant communities to the plant communities described here. Similarity index is determined by comparing the production and composition of a plant community to the production and composition of a plant community described in this site description. To determine Similarity index, compare the production (air dry weight) of each species to that shown in the plant community description. For each species, count no more than the maximum amount shown for the species, and for each group, count no more than the maximum amount shown for each group. Divide the resulting total by the total normal year production shown in the plant community description. If the rainfall has been significantly above or below normal, use the total production shown for above or below normal years. If field data is not collected at the end of the summer growing season, then the field data must be corrected to the end of the year production before comparing it to the site description. The growth curve can be used as a guide for estimating production at the end of the summer growing season.

The potential plant community on this site is a diverse mixture of native perennial grasses, shrubs, vines, trees and annual forbs and grasses. Smaller drainage-ways are dominated by desert trees like mesquite, desert willow and catclaw acacia. Larger washes and canyons will have a higher percentage of broadleaf trees like ash, walnut and netleaf hackberry.

State and transition model

6"), Sandy Wash

1a. CHG, introduction of a seed source, or direct seeding of exotic African lovegrasses, bermuda or Johnson grass.

1b. Unknown. Possible herbicide treatment of exotics species and seeding of native grasses.

2a. Poor condition watershed areas produce excess amounts of runoff causing channels to erode. As channels deepen stream terraces no longer flood. Trees and large shrubs still dominate. Perennial herbs are replaced by annuals and half shrubs.

Base level change in main stream causes down-cutting of bottoms. Poor condition watersheds can also deliver large amounts of Sediment to bottoms, destabilizing them and causing new channels to cut through the floodplain.

2b. PG/NG of watershed areas with or without shrub control planting of native grasses, maintenance treatments for shrubs, etc. Mechanical control of sheet, rill and gully erosion where possible. Reestablish flooding regime of bottoms.

CHG – continuous heavy grazing
PG/NG – proper grazing, no grazing

• annuals dominant,
• patches of some non-natives

MLRA 41-3 (12-1)

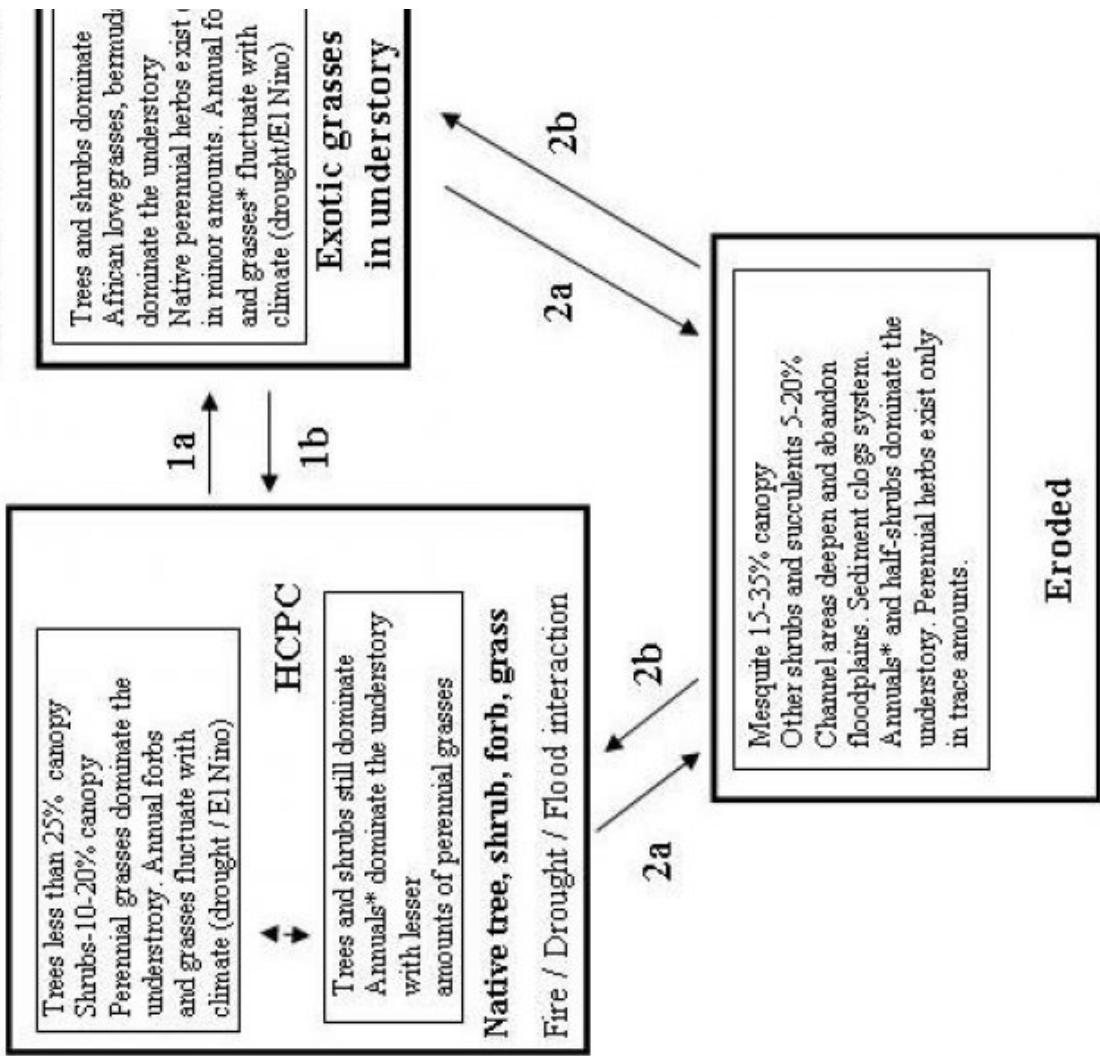

Figure 4. State and Transition, Sandy Wash 12-16" pz.

State 1 Historic Climax Plant Community

Community 1.1 Historic Climax Plant Community

The potential plant community of this site is a diverse mixture of perennial grasses, forbs, vines, trees and shrubs. Annual forbs and grasses of both the warm and cool seasons are well represented in the plant community. The major grass, forb and shrub species on the site are well dispersed throughout the plant community. The aspect is savannah. Periodic natural fires were important in maintaining a balance between woody species and herbaceous species. With continuous heavy grazing, palatable mid-grasses decline and species such as Rothrock grama, dropseed and threeawns increase. With severe deterioration, woody species increase to dominate the plant community. Mesquite, with lesser amounts of catclaw acacia and desert willow, form the over-story and burrowed dominates the under-story. Actively eroding areas become dominated by shrubs like burrobrush, rubber rabbitbush, batamote and desert broom. The site is very susceptible to gully, channel and bank erosion, especially where it has deteriorated to shrubby conditions and where depleted watershed areas are contributing larger than normal amounts of runoff. The lowering of the base level of the axial stream of a watershed will eventually cause channeling of the site. Deeply channelized areas will no longer flood the stream terraces of this site. Due to deep, coarse textured soils and extra moisture received as flooding, trees grow to maximum size on the site. This site can produce effective herbaceous covers with tree canopies up to 25%.

Table 5. Annual production by plant type

Plant Type	Low (Kg/Hectare)	Representative Value (Kg/Hectare)	High (Kg/Hectare)

State 2 Understory exotic perennial grasses

Community 2.1

Understory exotic perennial grasses

This state exists where perennial African grasses like bermuda grass and; Lehmann, Boer, Cochise and Weeping lovegrass, have either been seeded or have invaded from adjacent areas to become dominant in the under-story. These species usually have little effect on the over-story tree and large shrub component of the plant community. They do, however, greatly limit the diversity of native grasses and forbs.

State 3 Eroded

Community 3.1 Eroded

Figure 7. Sandy Bottom 12-16" pz, eroded

This state occurs where poor condition watersheds yield excessive amounts of runoff causing erosion of the channel areas. As channels deepen, the low stream terraces no longer receive extra water from flooding and stream-bank erosion enlarges the area of river-wash. Down-cutting of major stream systems can contribute to this situation in areas where sandy bottoms are tributary to the main stream. The woody component of the plant community usually remains intact but the herbaceous component becomes dominated by half-shrubs and annuals. Poor condition watersheds can also destabilize the sandy bottom site by adding more sediment than the system can handle, causing channels to move and cut through new areas on the floodplain.

Animal community

This site produces a wide variety of good quality forage and is usable at any season by all classes of cattle. It usually occurs as small inclusions within large areas of upland range sites. Having a good variety of forage species, shade, and occasional water, this site will be overused in the summer growing season before proper use is made of adjacent upland areas. For this reason, grazing systems must be used to allow recovery of herbaceous forage species on this site. The site produces a good variety of valuable browse for spring and fall use.

Occurring as occasional wooded strips through large areas of open uplands, this site is a haven for wildlife, especially in the heat of the summer season. Water is available occasionally in the spring and again in the summer. Water developments are very important for wildlife species using this site.

Hydrological functions

These sandy floodplains are extremely important for ground-water recharge in upland basins. Deep, very coarse

textured soils allow water to percolate to great depths after runoff from large storms.

Recreational uses

Hunting, hiking, horseback riding, bird-watching, camping, photography and picnicing.

Wood products

Mesquite and catclaw acacia furnish limited fuel-wood and posts. The importance of large trees on this site for wildlife should limit the fuel-wood uses to deadwood and driftwood.

Other products

Sand, magnetite.

Inventory data references

Range 417s include 1 in excellent condition, 1 in good condition and 4 in poor condition.

Type locality

Location 1: Pima County, AZ	
Township/Range/Section	T20S R8E S16
General legal description	Santa Margarita Ranch
Location 2: Pima County, AZ	
Township/Range/Section	T18S R17E S36
General legal description	Empire ranch at KA #20 in lower Mattie canyon.
Location 3: Pima County, AZ	
Township/Range/Section	T21S R8E S24
General legal description	Buenos Aires Nat. Wildlife Refuge
Location 4: Pima County, AZ	
Township/Range/Section	T18S R14E S36
General legal description	Santa Rita Experimental Range, bottom of Box canyon east of road # 486.

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

1. Number and extent of rills:

2. Presence of water flow patterns:

3. Number and height of erosional pedestals or terracettes:

4. Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):

5. Number of gullies and erosion associated with gullies:

6. Extent of wind scoured, blowouts and/or depositional areas:

7. Amount of litter movement (describe size and distance expected to travel):

8. Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values):

9. Soil surface structure and SOM content (include type of structure and A-horizon color and thickness):

10. Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff:

11. Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site):

12. Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):

Dominant:

Sub-dominant:

Other:

Additional:

13. **Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence):**

14. **Average percent litter cover (%) and depth (in):**

15. **Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production):**

16. **Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site:**

17. **Perennial plant reproductive capability:**
