

Ecological site R051XY317CO Foothill Loam

Last updated: 12/12/2024
Accessed: 05/13/2025

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

MLRA notes

Major Land Resource Area (MLRA): 051X–High Intermountain Valleys

This MLRA encompasses the San Luis Valley in south central Colorado and the Taos Plateau and Taos alluvial fans of north central New Mexico. As part of the northern portion of the Rio Grande Rift, the MLRA consists of large, alluvium filled basins washed down from adjacent mountain ranges. The Rio Grande River flows through this MLRA, continuing its long function of carrying mountain sediment down to the basin. Cenozoic volcanism is an extensive characteristic of the MLRA where large basalt flows with volcanic hills and domes are abundant. Ancient Lake Alamosa is a large feature within the MLRA.

Classification relationships

NRCS:

Major Land Resource Area 51, High Intermountain Valleys (United States Department of Agriculture, Natural Resources Conservation Service, 2006).

Southern Rocky Mountain Province

Ecological site concept

The Foothills Loam site occurs on what is considered the mountain-valley fan. Component landforms include: alluvial fans, fans, fan remnants, and mountain-slopes. Soils are mostly deep loam formed from alluvium from igneous and metamorphic rock. This site has a grass-shrub mix with grasses dominant and shrubs subdominant. Western wheatgrass is the most prevalent species. Others commonly present include: needleandthread, sedges, littleseed ricegrass, and blue grama. Some tree species may be present such as pinyon pine, juniper, and a few scattered Ponderosa pine.

Associated sites

R051XY233CO	Mountain Loam 10-18 PZ The Mountain Loam site occurs higher in the mixed conifer zone, versus the pinyon-juniper zone for the Foothill Loam. The mountain loam has a cool-season bunchgrass community.
-------------	--

R051XY279CO	Foothill Sand 9-12 PZ The Foothills Sand is sandwiched between the active dune field of the Great Sand Dunes and the Sangre de Cristo Mountains. There is a mix of both mountain alluvium and eolian surfaces blown in from the sand dunes.
R051XY278CO	Valley Bench 8-12 PZ The Valley Bench Site is usually a little lower in elevation and is drier. It is also prone toward a sagebrush community with degradation.
R051XY277CO	Basalt Hill 7-12 PZ The Basalt Hills site is associated with basalt flows. Soils are shallow to basalt bedrock.
R051XY283CO	Foothills 12-16 PZ The Foothills site is associated with basalt/volcanic formations. It is a deep to very deep soil formed from alluvium, derived from basalt/volcanic.

Similar sites

R051XY283CO	Foothills 12-16 PZ The Foothills site is associated with basalt/volcanic formations. It is a deep to very deep soil formed from alluvium, derived from basalt/volcanic.

Table 1. Dominant plant species

Tree	Not specified
Shrub	Not specified
Herbaceous	(1) <i>Pascopyrum smithii</i>

Physiographic features

This site occupies gently to moderately sloping fans and valleys in the pinyon-juniper zone. Much of it is in a position to receive water that runs off steeper land. Most of the time it is dry. Slopes are 0-10% generally, but occasionally it may range up to 35% slope. The Foothills Loam site occurs on the upper end of the slope, on what is considered the mountain-valley fan.

Table 2. Representative physiographic features

Landforms	(1) Alluvial fan (2) Mountain slope (3) Fan (4) Fan remnant (5) Stream terrace
Runoff class	Low to medium
Flooding frequency	None
Ponding frequency	None
Elevation	2,438–2,804 m
Slope	0–10%
Aspect	Aspect is not a significant factor

Climatic features

Average annual precipitation is 10 to 16 inches. Of this, more than half falls between May 1 and September 1, mostly as hard, spotty thundershowers in July and August. May and June are normally dry. Wide seasonal and yearly variations are common. Major native plants make most of their growth between early May and mid-July, although growth may continue through most of the summer, and there may be late regrowth of some early-maturing plants.

Mean annual temperature is 40 degrees to 43 degrees F. Average frost-free period is 80 to 103 days, from late May

to early June to September. Summer daytime temperatures are frequently in the low 80's, but rarely exceed 90 degrees F, and nights are cool. Temperatures of -20 degrees to -30 degrees F can be expected each year and are common some winters. Parts of the site are slightly warmer, though than lower valley land because of air drainage. Winds that often reach high velocities are common, especially in spring. Relative humidity is often low. Even so, evaporation rates average lower than those of many dry regions because of the cooler climate. There is usually more snow than at lower elevations, and snow is usually present during the coldest weather. However, snow cover is light through much of some winters.

Table 3. Representative climatic features

Frost-free period (characteristic range)	76-86 days
Freeze-free period (characteristic range)	100-102 days
Precipitation total (characteristic range)	254-406 mm
Frost-free period (actual range)	74-88 days
Freeze-free period (actual range)	99-103 days
Precipitation total (actual range)	254-406 mm
Frost-free period (average)	81 days
Freeze-free period (average)	101 days
Precipitation total (average)	330 mm

- (2) CERRO [USC00291630], Questa, NM

Influencing water features

This site does not have a water table.

Soil features

Soils are mostly deep loam, formed from alluvium from igneous and metamorphic rocks.

Most common parent materials are granite, gneiss and mica schist. Diagnostic features usually include a mollic epipedon and an argillic horizon. Surface textures is generally a loam, but fine sandy loam and clay loam are known to occur on this site.

Typical soils correlated to this site include:

Morval, Shawa and Jodero.

Table 4. Representative soil features

Parent material	(1) Alluvium–igneous and metamorphic rock
Surface texture	(1) Loam (2) Fine sandy loam (3) Clay loam
Family particle size	(1) Fine-loamy
Drainage class	Well drained
Permeability class	Moderately slow to moderate
Soil depth	152 cm
Surface fragment cover <=3"	0–10%
Surface fragment cover >3"	0–2%
Available water capacity (Depth not specified)	11.68–18.54 cm
Calcium carbonate equivalent (Depth not specified)	0–5%
Electrical conductivity (Depth not specified)	0–2 mmhos/cm
Sodium adsorption ratio (Depth not specified)	0
Soil reaction (1:1 water) (Depth not specified)	6.6–8.4
Subsurface fragment volume <=3" (Depth not specified)	0–10%
Subsurface fragment volume >3" (Depth not specified)	0–2%

Ecological dynamics

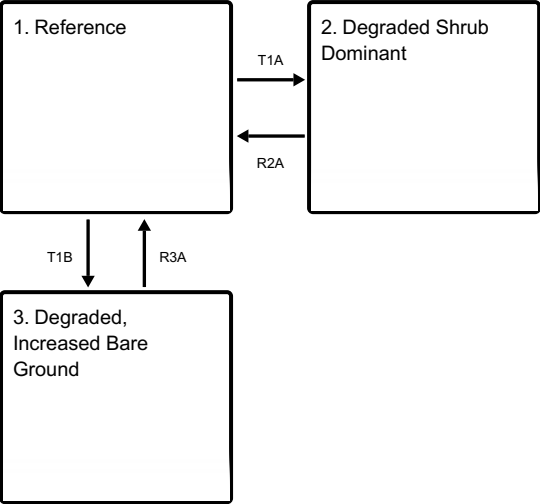

Organic matter has accumulated due to dense fibrous root systems with high annual turnover rates. This leads to high amounts of labile carbon, and an active microbial community. A diversity of forbs and shrubs also helps add organic matter, and feeds the microbial community which in turn, through processes such as mineralization provides plant available nutrients. Soil organic matter and root exudates such as glomalin help hold soil particles together and provides a high degree of aggregate stability.

All of these ecological processes help to provide an excellent medium for a diverse and healthy plant community. Most of all, argillic horizon can act as storage and gradual, long-term access even during times of drought. Also, due to the sites location on the landscape, flow-through water is often present from areas higher in elevation. This also aids in producing a diverse and productive site. Natural disturbances such as fire, drought, and various levels

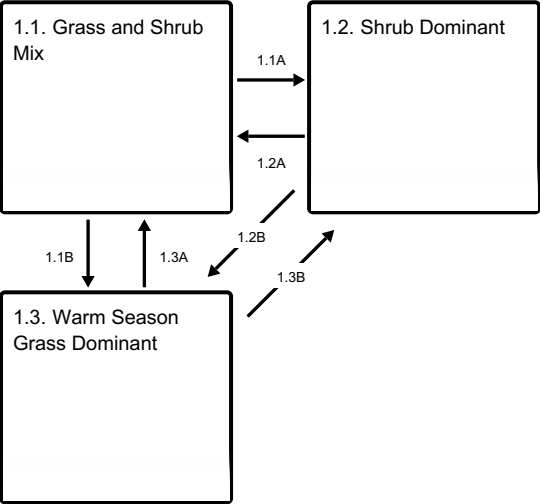

of herbivory are part of the ecosystem dynamics and a healthy site is resilient to these disturbances.

State and transition model

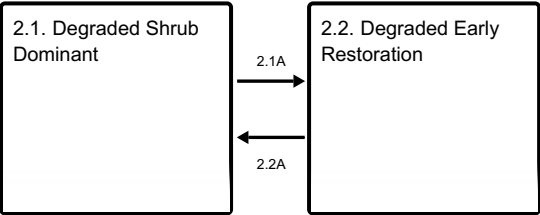

Ecosystem states

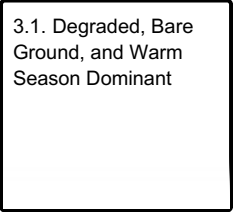

State 1 submodel, plant communities

State 2 submodel, plant communities

State 3 submodel, plant communities

State 1 Reference

Figure 7. Landscape shot of the Foothill Loam site

This state is a mix of grasses and shrubs with some forbs. Natural ecological dynamics from fire, drought, and herbivory cause the shrub density to fluctuate. Where the site has more frags in the profile or texture is a little courser, species such as needleandthread may become more dominant.

Resilience management. The reference state shows the greatest resilience to disturbance. A diversity of plant functional-structural groups create a diversity of root systems which in turn takes in resources and feeds microbial communities. Bare ground is minimal due to a high degree of cover and litter.

Dominant plant species

- fourwing saltbush (*Atriplex canescens*), shrub
- rubber rabbitbrush (*Ericameria nauseosa*), shrub
- western wheatgrass (*Pascopyrum smithii*), grass
- needle and thread (*Hesperostipa comata*), grass

Community 1.1

Grass and Shrub Mix

Figure 8. Reference Community: Grass-Shrub Mix

Figure 9. Reference Community in the foreground

This community is grass dominant with a mix of shrubs and forbs. Western wheatgrass is the major grass. Others commonly present are needle and thread, upland/dryland sedges, littleseed ricegrass, and blue grama. There may be small amounts of slender wheatgrass, Scribner needlegrass, muttongrass, Junegrass, squirreltail, Indian ricegrass, sand dropseed, mountain muhly, and Arizona fescue. Forbs are minor with buckwheat, loco weed, and lupine most prevalent. Of the scattered shrubs, fourwing saltbush and rubber rabbitbrush are most common. Others are wax currant, gooseberry, Greene's and Douglas rabbitbrush, winterfat, and skunkbush sumac.

Resilience management. This community is the most resilient to disturbance. Natural disturbance such as fire, drought, and herbivory from multiple classes of fauna, plays a role in maintaining the reference community. Healthy plant and soil dynamics keeps the site populated with a large diversity of plants and root systems which sustains the community through disturbance.

Table 5. Annual production by plant type

Plant Type	Low (Kg/Hectare)	Representative Value (Kg/Hectare)	High (Kg/Hectare)
Grass/Grasslike	673	1009	1345
Shrub/Vine	135	202	269
Forb	90	135	179
Total	898	1346	1793

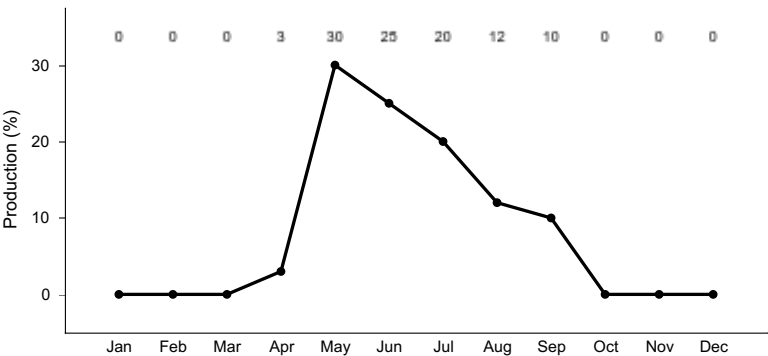

Figure 11. Plant community growth curve (percent production by month). CO5108, Cool-season Dominant Warm-season Subdominant, MLRA 51 Alluvial Fans & fan Remnants. Reference Plant Community for Chico Fan located in LRU 51-5 on fans and fan remnants above valley floor, pre-dominantly in areas surrounding Villa Grove and Saguache, Saguache County..

Community 1.2 Shrub Dominant

Figure 12. Shrub Dominant Community

Shrubs show increased cover and production with this community. Common shrubs include: fourwing saltbush, Greene’s rabbitbrush, rubber rabbitbrush, skunkbush sumac, wax current, winterfat, and Wyoming big sagebrush.

Resilience management. Shrubs provide cover which captures precipitation. They also have deep taproots to bring up moisture and nutrients which provides resilience during times of drought. As diversity decreases over time so does resilience.

Community 1.3
Warm Season Grass Dominant

Figure 13. Warm Season Grass Dominant

Figure 14. Warm Season Grass Dominant

Figure 15. Warm season grass dominant with rabbitbrush and juniper

This is a warm season dominant community. Blue grama dominates the site. Other species present include purple threeawn, galleta, mat muhly, and sand dropseed. Greene's and rubber rabbitbrush become dominant. Trees are common around this site and are located on shallow soils and/or skeletal soils. Tree species (two-needle pinyon, one-seed juniper, Rocky Mountain juniper, ponderosa pine and Douglas Fir) may begin to increase and occupy this site. If trees increase they are very minor.

Resilience management. This is considered an "at-risk" community phase. Long-term ecosystem drivers such as extended periods without fire and long-term herbivory targeted on palatable cool season species have created increased woody species, bare ground and erosion. Evergreens such as juniper, which are on the increase in this community can transpire throughout the year adding to the removal of moisture and contributing to droughty conditions. This community can no longer capture and maintain moisture like the community 1.1 and is therefore susceptible to crossing a threshold during an extended drought.

Pathway 1.1A Community 1.1 to 1.2

Grass and Shrub Mix

Shrub Dominant

Shrubs have slowly gained a competitive advantage due to deeper root systems which have the ability to access moisture and nutrients deeper in the profile than grasses. Extended periods between fire events will help give shrubs a competitive advantage.

Pathway 1.1B Community 1.1 to 1.3

Grass and Shrub Mix

Warm Season Grass Dominant

The greatest long-term driver is multiple years of grazing throughout the growing season. Preferred palatable species, such as western wheatgrass or needle and thread have less defense mechanisms than blue grama or purple threeawn. Eventually the site manifests itself with short-stature blue grama and increased bare ground. The shrubs have decreased due to disturbance such as fire, disease, excessive browsing, or human treatment.

Pathway 1.2A

Community 1.2 to 1.1

Shrub Dominant

Grass and Shrub Mix

Allowing fire into the system will set back shrubs and invigorate grass species. Other disturbances may be drought, disease, or excessive browsing.

Pathway 1.2B

Community 1.2 to 1.3

Shrub Dominant

Warm Season Grass Dominant

A disturbance, whether human caused or natural to decrease shrubs plus disturbance to decrease the palatable, cool season grasses.

Pathway 1.3A

Community 1.3 to 1.1

Warm Season Grass Dominant

Grass and Shrub Mix

The goal is to reestablish ecosystem diversity and production with attentive grazing management that includes monitoring and adaptive options to focus on cool season species reclamation. An average to above average precipitation year will help with the pathway.

Pathway 1.3B

Community 1.3 to 1.2

Warm Season Grass Dominant

Shrub Dominant

As fire frequency decreases, due to the lack of fine fuels, shrubs may find areas to germinate and grow. Once mature shrubs are established, basal sprouters, such as rabbitbrush, will gain a competitive advantage. Juniper may also increase due to extensive lateral and vertical root systems.

State 2

Degraded Shrub Dominant

Figure 16. Degraded Shrub Dominant

This site is dominated by bare ground and shrub species such as rubber rabbitbrush, Greene's rabbitbrush, and Wyoming big sagebrush. Bare ground is extensive. Warm season grasses are still present.

Resilience management. The site has crossed a threshold to a degraded state. A few resistant shrubs remain while bare ground and erosion is evident. Production and cover are both low.

Community 2.1 Degraded Shrub Dominant

Figure 17. Degraded Shrub State

Figure 18. Extensive bare ground and annuals between shrubs.

The Degraded Shrub Dominant community, at its worse is just a scattering of shrubs and annual forbs with large, continuous areas of bare ground.

Resilience management. Ecosystem health is very low as the site lacks the basic components to capture and maintain moisture. A few shrubs that have developed deep tap root systems remain and help anchor the site.

Community 2.2 Degraded Early Restoration

Figure 19. Western wheatgrass beginning to fill the spaces between shrubs.

Figure 20. Western wheatgrass re-colonizing between shrubs.

Restoration with the degraded shrub state begins with the re-establishment of western wheatgrass, a cool season rhizomatous species that can quickly begin to fill the spaces between shrubs and slow erosion.

Pathway 2.1A Community 2.1 to 2.2

Degraded Shrub Dominant

Degraded Early Restoration

Re-colonization of western wheatgrass during a good precipitation year.

Pathway 2.2A Community 2.2 to 2.1

Degraded Early Restoration

Degraded Shrub Dominant

Western wheatgrass has been set back due to drought or excessive herbivory.

State 3

Degraded, Increased Bare Ground

Figure 21. Degraded warm season dominant on convex position

Figure 22. Degraded warm season dominant on linear position

This state has crossed a threshold to a degraded state where bare ground is prevalent and warm season species is dominated by blue grama growing in a sod-forming fashion with low meristems and weak rhizomes. Other warm season grasses that may be present include threeawn and galleta.

Resilience management. Production and cover is low, bare ground and signs of erosion are evident. This state is highly susceptible to drought and further accelerated erosion.

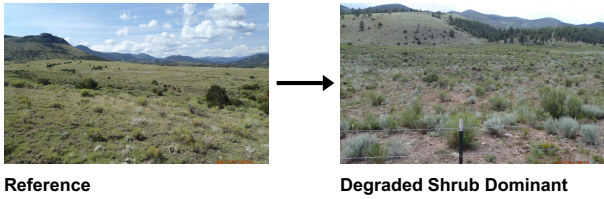

Community 3.1

Degraded, Bare Ground, and Warm Season Dominant

The community has crossed a threshold to a degraded state where bare ground is prevalent and warm season species is dominated by blue grama growing in a sod-forming fashion with low meristems and weak rhizomes. Other warm season grasses that may be present include threeawn and galleta.

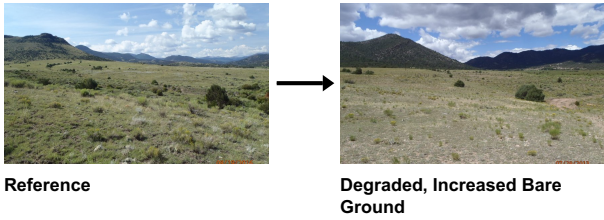

Transition T1A

State 1 to 2

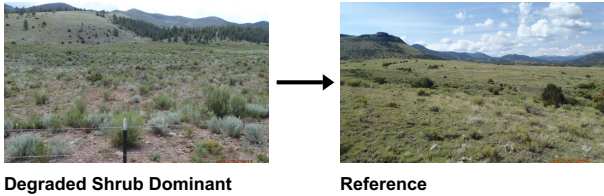

Slow drivers include a reduced fire regime, often due to the lack of fine fuels; repetitive defoliation and high utilization of palatable species by domestic livestock, especially during drought; and soil destabilizing factors such as erosion.

Transition T1B State 1 to 3

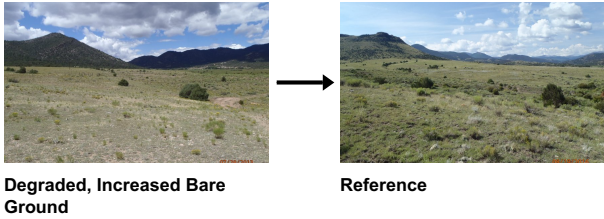

Long term drivers such as constant defoliation of preferred species, especially on convex positions which warm up faster in the spring and collect less precipitation in the winter, will degrade toward a bare ground-blue grama dominant site. Blue grama with low meristems and weak rhizomes will persist in these harsher convex areas.

Restoration pathway R2A State 2 to 1

Long term management that improves ecosystem function. This includes restoring soil health and plant diversity. Western wheatgrass is often the first grass to begin recolonization in bare areas, re-establishing a network of rhizomes to begin restoration of site ecological processes. Careful management of grazing plus a possible re-introduction of fire into the systems will be needed for restoring plant and soil health.

Restoration pathway R3A State 3 to 1

A long-term management system that monitors and adapts to periodic disturbance such as drought. Establishment of ground cover, plant diversity, soil organic matter, and aggregate stability is important to re-establishing ecosystem function.

Additional community tables

Table 6. Community 1.1 plant community composition

Group	Common Name	Symbol	Scientific Name	Annual Production (Kg/Hectare)	Foliar Cover (%)

--Site Development and Testing Plan--:

Future work to validate and further refine the information in this Provisional Ecological Site Description is necessary. This will include field activities to collect low-, medium-, and high-intensity sampling, soil correlations, and analysis of that data.

Additional information and data are required to refine the Plant Production and Annual Production tables for this ecological site. The extent of MLRA 51 must be further investigated.

Field testing of the information contained in this Provisional ESD is required. As this ESD is moved to the Approved ESD level, reviews from the technical team, quality control, quality assurance, and peers will be conducted.

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

- 1. Number and extent of rills:** None to slight. Some minor rilling may be found on steeper slopes. Widely spaced and short.

- 2. Presence of water flow patterns:** Typically none on gentle slopes. Expect flow paths on steeper slopes following intense storms. Flow patterns are short and not connected. Debris obstructions present.

- 3. Number and height of erosional pedestals or terracettes:** Pedestalled plants may exist in or near flow paths. Minor.

- 4. Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):** 20% or less bare ground, with bare patches ranging from 6-10 inches in diameter. Prolonged drought or wildfire events will cause bare ground to increase upwards to 20-30% with bare patches ranging from 10-12 inches in diameter.

- 5. Number of gullies and erosion associated with gullies:** None to slight. Gullies caused by off-site drainage may exist, caused by natural events. Gullies shallow with blunted edges and re-stabilizing.

6. **Extent of wind scoured, blowouts and/or depositional areas:** None
-
7. **Amount of litter movement (describe size and distance expected to travel):** Typically short at 1-3 feet following intense storms.
-
8. **Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values):** Stability class rating anticipated to be 4-5 in interspaces at soil surface.
-
9. **Soil surface structure and SOM content (include type of structure and A-horizon color and thickness):** These soils have a high water holding capacity and moderate permeability. Surface soil texture typically ranges from loam, fine sandy loam or clay loam. The A-horizon averages 0-13 inches in depth with a dark brown to dark grayish brown color. Structure ranges from a weak fine granular, moderate fine granular; to strong medium granular structure
-
10. **Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff:** The composition/distribution of cool rhizomatous grasses, bunchgrasses and shrubs tend to slow overland flow and moderate runoff. Diverse canopy structure reduces raindrop impact allowing for increased time for infiltration.
-
11. **Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site):** None
-
12. **Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):**
- Dominant: cool season rhizomatous grass >
- Sub-dominant: cool season bunchgrass > shrubs = warm season bunchgrass >
- Other: forbs > trees
- Additional:
-
13. **Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence):** Minimal. Extended drought will increase plant mortality. Decadence can occur on areas void of grazing disturbance.
-
14. **Average percent litter cover (%) and depth (in):** 30-40% litter cover at 0.25 inch depth. Litter depth will increase under shrubs and trees. Litter cover during and following drought can range from 15-20% and 5-15% following wildfire.
-
15. **Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production):** 800 lbs./ac. low precipitation years; 1200 lbs./ac. average precipitation years; 1,600 lbs./ac. high

precipitation years. After extended drought, production will be reduced by 200 – 400 lbs./ac. or more.

16. **Potential invasive (including noxious) species (native and non-native).** List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site: Juniper species, pinyon, rabbitbrush.
-
17. **Perennial plant reproductive capability:** The only limitations are weather-related, wildfire, natural disease, inter-species competition, wildlife, and insects that may temporarily reduce reproductive capability.
-
